Problem 1

Flowers:

<https://codeforces.com/problemset/problem/474/D>

Main Idea

- Let $dp[i]$ represent number of ways in which Marmot can eat i flowers.
- Now $dp[i]$ will be sum of two values $dp[i-1]$ (i.e. just add one **red** flower to the bunch of **$i-1$** flowers) and $dp[i-k]$ (i.e. add **k** white flowers to the bunch of **$i-k$** flowers).

$$k=2, n=4$$

$\{RRRR\}, \{WWRR\}, \{RRWW\},$
 $\{RWWR\}, \{WWWW\}.$

dp[i] $\rightarrow$ no. of ways to eat i flowers.

Problem 2 [CSES]

Removal Game:

<https://cses.fi/problemset/task/1097>

Main Idea

- The dp function can calculate the optimal values for states of only a single player.
- Therefore, we must simulate the optimality of the second player on our own.
- We can do this by considering both cases of the second person once the move of the first person is chosen and then take the maximum of those two.
- In this way, the dp is called always 2 steps further.

1st person,

$$i = 0, j = n-1,$$

↓ ↓ ↓
1st 2nd 1st

$$\begin{aligned} a[i] &\rightarrow \underline{a[i+1] \text{ or } a[j]} \\ a[j] &\rightarrow \underline{a[i] \text{ or } a[j-1]} \end{aligned}$$

$$\rightarrow \underline{\underline{(\max)(\underline{a[i]} + \boxed{dp(3^{\text{rd}} \text{ turn})}, \underline{a[j]} + dp(3^{\text{rd}} \text{ turn}))}}$$

↓
2nd

$$\max \left(\underbrace{a[i]}_{\text{1st}} + \underbrace{\min(dp[i+2, j], dp[i+1, j-1])}_{\text{2nd}}, \right. \\ \left. \underbrace{dp[i, j]}_{\text{1st}} + \underbrace{\min(a[j], \min(dp[i+1, j-1], dp[i, j-2]))}_{\text{2nd}} \right)$$

$$(S_1) + S_2 = \text{constant} \\ \text{Sum of array}$$

Problem 3 [Atcoder DP Contest]

Knapsack 2:

https://atcoder.jp/contests/dp/tasks/dp_e

Main Idea

- Instead of taking the standard state space and transition (finding the maximum value for a given $(i, \mathbf{w})$ pair, we will form a different pair of states.
- Find for every $(i, \mathbf{val})$ pair, the minimum weight from which it could be obtained.
- This will work in the given constraints.
- Update the transitions according to this as well.

$dp[i][j] \rightarrow$

maximum possible value
if we consider only first i items
and fill j units of weight.

$dp[i][j] \rightarrow$

minimum weight to obtain j value
while considering first i items.

$dp[i][j] \rightarrow dp[i-1][j - wt[i-1]] + val[i-1]$
 $old \rightarrow dp[i-1][j]$

$dp[i][j] \rightarrow wt[i-1] + dp[i-1][j - val[i-1]]$
 $dp[i][j] \rightarrow dp[i-1][j]$
 new
